This construction utilizes a fully supported, strain free wire wound sensing element encapsulated in a compacted MgO insulated metal sheathed cable. This combination provides a probe suitable for extremely demanding applications. It offers superior resistance to pressure, shock and vibration. By utilizing the finest elements available, this style of probe displays long life, long term accuracy and excellent repeatability.

## LEADWIRE EFFECT

Leadwire error can have a significant effect on RTD performance. Since an RTD is a resistance type sensor, introducing leadwire between the RTD and instrument will add additional resistance to readings. Also, additional resistance is not constant but increases with ambient temperature.

To estimate leadwire error for a 2-wire configuration, multiply the total length of the extension leads by the resistance per foot in the table on the previous page. Then divide by the sensitivity of the RTD, given in the table on the previous page to obtain an error in °C.

Example: 100Ω platinum RTD with a TCR of 0.00385 and 50 ft. of 22 AWG leadwire.

$$R = 50 \text{ ft.} \times 0.0165\Omega/\text{ft.} = 0.825\Omega$$

$$\text{Approximate error} = 0.825\Omega / 0.385\Omega = 2.14^\circ\text{C}$$

In most cases, you can cancel leadwire resistances by using a 3 or 4-wire configuration. Another way to deal with long leadwire runs is with a 2-wire current transmitter. Its linearized signal is not affected by leadwire resistance and electrical noise and is suitable for use in installations requiring several hundred feet or more of leadwire.

## WIRING CONFIGURATIONS AND CHARACTERISTICS (See illustration on the following page)

### 2-WIRE CONFIGURATION

An RTD in a 2-wire configuration is the least accurate style of RTD assembly. The added lead wire resistance is not compensated for by the temperature controller or transmitter used to monitor the resistance of the RTD. This increased resistance will cause the display temperature to be higher than the actual temperature.

### 3-WIRE CONFIGURATION

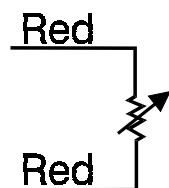

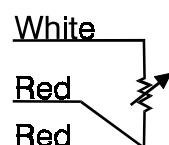

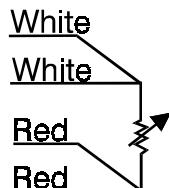

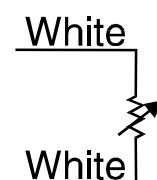

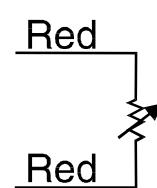

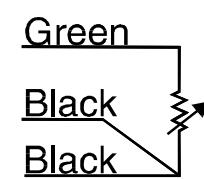

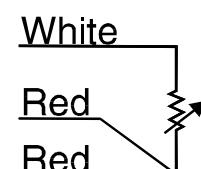

An RTD in a 3-wire configuration is the most common configuration because it is both cost effective and accurate. The added lead wire resistance is calculated by the controller through the third wire of the RTD assembly. The leadwire resistance is then subtracted from the loop resistance and true resistance is found. Through this method the controller or transmitter "compensates" the lead wire giving an accurate temperature display. SensorTec generally matches resistance between leadwires to ± 5% to ensure accurate metering.

### 4-WIRE CONFIGURATION

An RTD in a 4-wire configuration not only cancels leadwire resistance, but removes the effects of mismatched resistances such as contact points. 4-wire circuits are recommended for high accuracy sensors and are usable over longer distances than 3-wire circuits.
